INTERNATIONAL UNION FOR THE PROTECTION OF NEW VARIETIES OF PLANTS
GENEVA**TECHNICAL WORKING PARTY
FOR
ORNAMENTAL PLANTS AND FOREST TREES****Thirty-Eighth Session
Seoul, September 12 to 16, 2005****PROJECT TO CONSIDER THE PUBLICATION OF VARIETY DESCRIPTIONS:
MODEL STUDY ON ALSTROEMERIA***Document prepared by expert from Netherlands*

1. In the model study on Alstroemeria descriptions were requested for 7 varieties which had been plant breeders' rights in Canada, Japan, the Netherlands and South Africa.
2. Descriptions of the following varieties were received:

Stabec:	a pink flowered variety used for cut flower production
Stamond:	a white flowered variety used for cut flower production
Staprilan:	a yellow flowered variety used for production of pot plants
Staprinag:	a white flowered variety used for production of pot plants
Staprasis:	a white flowered variety used for production of pot plants
Stasach:	a red flowered variety for production of cut flowers
Statiren:	a pink flowered variety for production of cut flowers

3. The following photographs and additional documentation on the growing of the plants (as far as available) were received from 3 countries:

Canada

- Color photographs were taken by the testing centre.
- The plants were grown in summer/Fall in pots or open greenhouse; all in 5 gallon pots; duration of growth 4 to 6 months.
- Minimum temperature 12 C; full sunlight.
- Pot varieties are grown in the same way as varieties for cut flower production, the only difference being a smaller pot for the pot types (10 inch pot)

Japan

- No pictures were made at the testing centre
- In Japan there is normally on-site inspection
- The applicants are given the following information: Planting in the greenhouse, number of plants and spacing.
- Planting time: Spring: May; or Autumn: September

Netherlands

- Photographs from the testing centre.
- Growing in autumn/winter/spring in the greenhouse
- Temperature low, to be kept free from frost in winter.
- No shading
- Flowering in April/May
- Pot varieties are treated in the same way as varieties grown for cut flower production: both are grown in the open greenhouse soil.

Results

4. The survey of the data received from the different countries is provided as Annex I. Annex 2 provides selected characteristics, which include those characteristics which will be retained in the new draft Test Guidelines and the non-asterisked characteristics in that draft.
The UPOV Color Groups have been added where applicable.

Discussion

Char. 1 Stem length

RSA scores 3 for the pot varieties. That is interesting as these varieties are expected at the bottom of the scale. No further information has been received from RSA.
For the cut-flower varieties Japan scored lower than the Netherlands, perhaps due to different growing circumstances.

Char. 8 Umbel branches: number

Rather consistent scores.

Char. 9 Umbel branches: length

Some variation; length is strongly depending on the time of observation.

Char. 10 Pedicel: length

Same comment as for Char. 9.

Char. 11 Flower: main color

Stabec: note 6, red, appears to deviate compared to notes 7 and 8 light pink and pink. Perhaps the red blotch on a pink background is impressive and, whilst not covering the largest part of the flower, has been the basis of the decision here.

Staprinag: the same as for Stabec, but in this case, there is a light pink blotch on a white background.

For the other varieties there may often be confusion by taking the most impressive color instead of the color that is covering the largest part of the surface. In addition, there is difficulty in the cases where 2 colors cover the surface on a 50/50 basis.

Char. 12 Size

Rather consistent scores.

Char 14 Outer tepal: Shape of blade

Hopefully attention will be paid in the shape document to the distinctness between the shapes mentioned here. The same remark on the distinctness between claw and blade.

Char. 16 Main color of inner side of blade

The confusion that can be seen here has been already been solved in the revised draft by dividing the petal into several parts for color observation

Char. 18 Outer tepal: number of stripes on inner side of blade

The same as for Char. 16: division in parts and better definition

Char. 20 Inner lateral tepal: main color of inner side of middle zone of blade

Not so much variation as far as the color groups are concerned. Yellow orange for Stasach is questionable.

Char. 22 Inner lateral tepal; size of stripes on inner side of blade.

Rather large variation in states, which has been addressed in the new draft Test Guidelines by division into parts and better definition of the characteristic.

Char. 23 Stamen: main color of filament

Some understandable variation in states

Char. 25 Stamens: color of the anthers at the start of dehiscence

This characteristic is very dependent on the time of observation. The color of the pollen is *not* meant here.

Char. 26 Anthocyanin coloration of the ovary.

Extremely variable results, which has been addressed in the draft Test Guidelines by a more precise definition.

General

It appears that the differences may be partly caused by different environmental factors between the different testing locations but also by unclear definitions of characteristics and/or the indication of the time of observation.
